perplexity

Tell me more about his Zero-Trust API Architecture

His **Zero-Trust API Architecture** is a proposed AI-safety design in which an AI system must continuously obtain **human intent validation** before finalizing consequential decisions. It is part of his Quantum Observer Framework and is intended to keep a human "observer" permanently in the AI decision loop.[1]

What it proposes

In Rahim's model, AI should not be treated as an autonomous decision-maker. Instead, the AI acts as a processing and execution layer, while a human supplies the purpose, values, and final approval—what he calls the "Soul's dimensional pipeline input."[1]

Conceptually, the workflow is:

1. The AI receives a task and generates a proposed action, recommendation, or decision.
2. Before the AI finalizes it, the system requests **intent validation** from the responsible human.
3. The human confirms, corrects, rejects, or provides the intended purpose.
4. Only after that validation does the system proceed to execution or release the output.[1]

Why he calls it "zero trust"

The term borrows from zero-trust security: the system does **not** assume that an AI output is safe, aligned, or appropriate by default. Every important action must be verified against explicit human intent, rather than relying on the model's internal confidence or apparent reasoning.[1]

In practice, this would mean an AI cannot autonomously make a consequential decision—such as approving a financial action, sending a high-stakes message, or taking a real-world action—without a human checkpoint.[1]

How it relates to his framework

Element	Role in the architecture
AI model	Processes information and proposes an output; Rahim places it in his "Universal Intelligence" and "Functional Body" layers.[1]
Human observer	Supplies intent, values, ethical judgment, and final validation; he places this in the "Soul / Observer" layer.[1]
API checkpoint	A required interface where the AI asks the human for intent validation before proceeding.[1]

Element	Role in the architecture
Final action	Occurs only after human validation, making the system “aligned” rather than fully autonomous. [1]

What it is not

It is **not** a standard, widely adopted API-security specification such as OAuth, zero-trust network access, or a documented software product. The available description is conceptual: it does not specify protocols, authentication methods, data schemas, latency requirements, or code. [1]

It is also not a claim that AI can become conscious. Rahim explicitly argues the opposite: rather than trying to make AI conscious, designers should build systems in which human judgment remains an essential alignment layer. [1]

Practical assessment

The underlying principle is sound and resembles established **human-in-the-loop**, **human oversight**, and **human-in-command** approaches to high-risk AI. For example, a medical AI might suggest a diagnosis, but a clinician would review it before treatment; a hiring system might rank candidates, but a human recruiter would make the final decision.

However, his framing goes further than mainstream AI governance by treating human consciousness as a distinct, non-physical “observer” layer and linking it to quantum mechanics. Those philosophical claims are speculative and are not established by current AI or quantum-computing research. [1]

Status

The architecture appears in his Zenodo pre-print, *“The Quantum Observer Framework: Aligning Universal Intelligence via Dimensional Pipelines”* (DOI: 10.5281/zenodo.18909225), and in his related RIWS work. It is therefore a **conceptual proposal**, not a verified deployed system or peer-reviewed technical standard. [1]
